## <stdint.h> (1)

Este *header file* contiene definiciones de tipos de datos que nos dicen explícitamente su tamaño

## <stdint.h> (1)

Este *header file* contiene definiciones de tipos de datos que nos dicen explícitamente su tamaño

```
char caracter = 8;  
short corto  = 16;  
int entero   = 32;
```

VS

```
int8_t ochoBits = 8;  
int16_t unoSeisBits = 16;  
uint32_t uTresDosBits = 32;
```

## <stdint.h> (1)

Este *header file* contiene definiciones de tipos de datos que nos dicen explícitamente su tamaño

```
char caracter = 8;  
short corto  = 16;  
int entero   = 32;
```

VS

```
int8_t ochoBits = 8;  
int16_t unoSeisBits = 16;  
uint32_t uTresDosBits = 32;
```

Este approach a los tipos de datos mejoran la **legibilidad, robustez** y **portabilidad** del código

## <stdint.h> - Familias

```
int8_t ochoBits;
```

```
int_least8_t almenosOcho;
```

```
int_fast8_t fastOcho;
```

| Familia   | Tamaño                                                                      | Presencia                                    |
|-----------|-----------------------------------------------------------------------------|----------------------------------------------|
| N_t       | N bits garantizados                                                         | Solo si la implementación puede garantizarlo |
| _leastN_t | Al menos N bits, puede ser mayor                                            | Siempre definido                             |
| _fastN_t  | Al menos N bits, elegido para que dar la mayor velocidad en la arquitectura | Siempre definido                             |

# Booleans (1)

→ Los booleanos son variables que pueden tomar 2 valores: **True** o **False** En C, los booleanos no existen como un tipo de datos en sí mismo, pero los estamos usando constantemente, cada vez que empleamos operadores como `<` , `>` , `==` , etc.

```
if (a < b)
    printf("a<b");
```

1. se evalua la expression `a < b`  
si `a < b`  $\Rightarrow$  True  
si `a >= b`  $\Rightarrow$  False
2. if (resultado de evaluar la expresion)  
if (True)  $\Rightarrow$  se entra en la condicion  
if (False)  $\Rightarrow$  no se entra en la condición

```
int a = 5, b = 3;

int bool = a < b;
    → bool = 0; //False

bool = a > b;
    → bool = 1; //True
```

## Booleans (2)

```
1  #include <stdio.h>
2
3  √ int main (void){
4      int a = 1;
5      float b = 0.0;
6      char c = 'a', d = '0';
7
8      if(a)
9          printf("%d (int)\t\t is considered true\n", a);
10
11     if(b)
12         printf("%f (float)\t is considered true\n", b);
13
14     if(c)
15         printf("%c (char)\t is considered true\n", c);
16
17     if(d)
18         printf("%c (char)\t is considered true\n", d);
19     return 0;
20 }
```

obs. En C todas las variables distintas de 0 son consideradas **True**.

## Booleans (3) - Coding Style Guides

```
size_t length = 5; /* Counter variable */
uint8_t is_ok = 0; /* Boolean-treated variable */

if (length)        /* Wrong, length is not treated as boolean */
if (length > 0)     /* OK, length is treated as counter variable containing multi values, not only 0 or 1 */
if (length == 0)    /* OK, length is treated as counter variable containing multi values, not only 0 or 1 */

if (is_ok)         /* OK, variable is treated as boolean */
if (!is_ok)        /* OK, -||- */
if (is_ok == 1)    /* Wrong, never compare boolean variable against 1! */
if (is_ok == 0)    /* Wrong, use ! for negative check */
```

if (length != 0)

# Structs y Unions

# Structs (1)

**def.** Las structs son un tipo de dato compuesto en C que agrupa, en sí misma, un grupo de variables bajo un mismo nombre. Estas variables pueden ser de distinto tipo, lo que hace que las structs sean muy útiles para crear conjuntos de datos complejos que representen objetos o registros.

Una ventaja importante de las structs es que permiten a una función retornar varios datos agrupados en una variable.

## Structs (2) - example

```
struct persona{  
    char nombre[20];  
    int edad;  
    float altura;  
};
```

```
struct persona p1 = {  
    .nombre = "Felipe",  
    .edad = 25,  
    .altura = 1.8  
};
```

```
/* Una forma de equivalente de inicializar un struct es: */  
struct persona p2 = {"Marco", 24, 1.75};
```

## Structs (3) - con padding

```
struct persona{  
    char nombre[50];  
    int edad;  
    float altura;  
};
```

```
struct persona p1 = {  
    .nombre = "Felipe",  
    .edad = 25,  
    .altura = 1.8  
};
```

```
/* Una forma de equivalente de inicializar un struct es: */  
struct persona p2 = {"Marco", 24, 1.75};
```

struct persona

# Unions (1)

**def.** Las unions son un tipo de datos similares a las structs en el sentido en que agrupan varios tipos de variables dentro de sí mismas, sin embargo, hay una diferencia clave: el espacio que ocupan en memoria.

Las unions, a diferencia de las structs, ocupan un único lugar en memoria, de tamaño igual al de la variable más grande que la misma contenga.

## Unions (2) - example

```
union documento{
    int dni;
    char pasaporte[11];
};

union documento mi_doc = {.dni = 45548596};
printf("%d\n", mi_doc.dni);

strcpy(mi_doc.pasaporte, "C4313AAK10");
printf("%s\n", mi_doc.pasaporte);
```

## Unions (2) - example

```
union documento{  
    int dni;  
    char pasaporte[11];  
};
```

```
→ union documento mi_doc = {.dni = 45548596};  
printf("%d\n", mi_doc.dni);
```

```
strcpy(mi_doc.pasaporte, "C4313AAK10");  
printf("%s\n", mi_doc.pasaporte);
```

## Unions (2) - example

```
union documento{  
    int dni;  
    char pasaporte[11];  
};
```

```
union documento mi_doc = {.dni = 45548596};  
printf("%d\n", mi_doc.dni);
```

```
→ strcpy(mi_doc.pasaporte, "C4313AAK10");  
printf("%s\n", mi_doc.pasaporte);
```

## Unions (3) - example

```
union documento{  
    int dni;  
    char pasaporte[11];  
};
```

```
union documento mi_doc = {.dni = 45548596};
```

→ strcpy(mi\_doc.pasaporte, "C4313AAK10");

```
printf("%d\n", mi_doc.dni);    ???  
printf("%s\n", mi_doc.pasaporte);
```

# Uso de typedef

```
/* Uso de typedef */
typedef struct{
    char nombre[20];
    int edad;
    float altura;
}persona_t;

typedef union{
    int dni;
    char pasaporte[11];
}documento_t;

int main(void){
    documento_t mi_doc = {.dni = 45548596};
    persona_t p1;
    strcpy(p1.nombre, "p1pe");
    p1.edad = 25;
    p1.altura = 1.8;

    printf("%d - dni\n", mi_doc.dni);
    printf("%s - nombre", p1.nombre);
}
```

Utilizando *typedef* puedo crear mi propio tipo de dato customizado.

# Ejemplo de uso - Manejo de Registros

```
typedef union{
    struct{
        uint32_t ISR;
        uint32_t IFCR;
        struct{
            uint32_t CCR;
            uint32_t CNDTR;
            uint32_t CPAR;
            uint32_t CMAR;
            uint32_t RESERVED;
        } CHN[8];
    } REGs;
    uint32_t page_reserved;
}ejemplo_registro_t;
```

```
ejemplo_registro_t ejemplo;
uint32_t valor = ejemplo.REGs.CHN[6].CNDTR;
```
